

Horse rescue administrator discovers nature's way of dealing with common allergic reaction.

From April through October, horses often develop a skin condition called sweet itch. It's caused by tiny biting gnats or midges. There are more than one thousand species of them in the *Culicoides* genus.

Until now, treatments have been limited to managing the symptoms instead of dealing with the cause. When electrolyte salts present in a horse's normal perspiration are correctly balanced, the horse has a natural defense against bacteria, fungus, skin microbes and even gnats. Even the eyes are protected by salt in the tears.

Sweet itch and other skin conditions can develop when that delicate electrolyte balance is compromised. Feeding more electrolytes simply can't restore this critical balance but, when the horse's own electrolytes are precisely balanced to work correctly, many such conditions will disappear.

Equiwinner™ does that. It's a simple, effective dermal patch that regulates the horse's electrolytes to restore that proper balance as nature intended. It produces amazing results, often in 10 days or less.

June 2018 - Equiwinner Delivers Effective Treatment Against Sweet Itch
